**Chief Complaint:** New floaters in both eyes.

**History of Present Illness:** A 60-year-old gentleman with a history of hepatitis C virus (HCV) infection presents with new floaters in both eyes. He started treatment for HCV with peginterferon and ribavirin 6 weeks prior to this visit.

Four weeks prior to this visit, the patient was seen in our eye clinic at the University of Iowa for a history of floaters and a few episodes of “prisms of light” in both eyes lasting for 5 to 10 seconds. His examination at that time, which included a detailed funduscopy examination, was unremarkable.

The patient was instructed to return to clinic in 2 weeks for a reevaluation, but returned in 4 weeks instead. At this follow up visit he reported that the floaters had resolved.

**Past Ocular History:** Presbyopia, no previous ocular surgeries, no trauma

**Past Medical History:** Hepatitis C virus, tobacco use

**Medications:** Erythropoetin, peginterferon, ribavirin

**Allergies:** No known drug allergies

**Family and Social History:** Non-contributory

**Slit lamp Examination:**

- Visual acuity, without correction:
  - OD: 20/20-2
  - OS: 20/40, with pinhole 20/20
- IOP: 12mmHg OD, 11mmHg OS
- Pupils: 3 mm → 2 mm, brisk, equal with no relative afferent pupillary defect
- Confrontation visual field: Full OU
- Extraocular movements: Full OU
- External exam: Normal OU
- Slit lamp exam:
  - Lids/lashes: Normal OU
  - Conjunctiva: Normal OU
  - Sclera: Normal OU
  - Cornea: Clear OU
  - Anterior chamber (AC): Deep and quiet OU
Dilated Fundus (Figure 1)

- Disc: pink, sharp borders, multiple cotton wool spots (CWS) surrounding the nerve, small areas of retinal hemorrhages around the nerve OU
- Cup to disc ratio: 0.3 OU
- Macula: flat OU, few CWS encroaching upon the macula OU
- Vessels: normal OU
- Periphery: normal OU

Discussion:

The differential diagnosis for diffuse CWS surrounding the optic nerves in both eyes (Figure 1) includes: interferon-associated retinopathy, hypertensive retinopathy, retinopathy associated with leukemia/lymphoma, ocular ischemia, Purtscher's retinopathy (insert link to our Eyerounds case) and HIV retinopathy. Given that the patient had recently started interferon therapy, was HIV negative, had a normal blood pressure and blood cell count and had no risk factors for ocular ischemia or Purtscher’s retinopathy, the most likely diagnosis was interferon-associated retinopathy.

Hepatitis C virus (HCV) primarily affects the liver. However, patients infected with HCV are often asymptomatic, and the disease frequently goes unnoticed until severe scarring of the liver (cirrhosis) occurs. There is no cure for HCV; however, various medications can be used to decrease the viral load. A common treatment regimen includes a combination of interferon and ribavirin (Schulman et. al. 2001).

Many reports have discussed the ocular complications associated with interferon use as an antiviral or antiangiogenic agent. Ikebe first reported this condition in a 39-year-old gentleman who developed retinopathy after administration of intravenous interferon (Ikebe et. al. 1990). Other complications associated with
Interferon include ischemic optic neuropathy, subconjunctival hemorrhage, retinal hemorrhage, combined choroidal and retinal perfusion deficits and cystoid macular edema (Guyer et al. 1993, Schulman et al. 2001, Tokai et al. 2001). Interferon associated retinopathy occurs in 19% to 69% of adults on interferon therapy (Narkewicz et al. 2010, Schulman et al. 2001).

Interferon-associated retinopathy often presents with cotton wool spots, retinal hemorrhages and other retinal microvascular irregularities (Esmaili et al. 2001). These changes occur most notably around the optic nerve head and in the posterior pole (Schulman et al. 2001). The retinopathy typically presents 3 to 5 months after treatment begins; however, as in our case, it can present as early as 2 to 6 weeks into the treatment (Kadayifcilar et al. 1999, Okuse et al. 2006).

Frequent monitoring of patients on interferon is important. Patients with normal exams should be followed every 4 to 6 months while those with retinopathy should be followed more frequently while on treatment. Fortunately, the ocular findings of interferon-associated retinopathy appear to reverse with cessation of treatment, including CME in one case (Tokai et al. 2001). When the cotton wool spots encroach upon the macula or when CME is present, it is important for the ophthalmologist to work with the internal medicine team and consider terminating interferon treatment (Meltzer et al. 2008).

**Communicating with Internal Medicine**

Our patient’s HCV disease was advanced, and the hepatologist felt that the patient had a guarded prognosis despite interferon treatment. The patient’s initial hepatitis C viral load was very high (>1 million IU/mL). However, after only 6 weeks of treatment (around the same time that the retinopathy was noted), his viral load became undetectable. We were concerned about visual prognosis as the CWS were close to the macula, but the hepatology service, understandably, had hoped to continue treatment given its success.

Extensive discussions took place between the patient, his family and the hepatology and ophthalmology services. An attempt was made to weigh the potential risk to the eye against the significant benefit of decreased viral load and activity of HCV while on peginterferon. After careful deliberation, the patient decided to continue with the HCV treatment for now, considering his great response thus far and the likelihood that he would not need to be on the treatment for an extended period of time. The ophthalmology service agreed to closely monitor the patient for CME and other signs of worsening interferon-associated retinopathy.

Fortunately on examination 2 weeks later (8 weeks into interferon therapy) the interferon retinopathy was stable if not a bit better (Figure 2).
Our ophthalmology service will continue to monitor the retinal exam every 4 to 8 weeks and communicate closely with the internal medicine service.

**Diagnosis:** Interferon-associated Retinopathy

<table>
<thead>
<tr>
<th>Epidemiology</th>
<th>Signs</th>
</tr>
</thead>
</table>
| - No age/gender predilection  
- Pre-existing arteriosclerosis that affects microcirculation may promote development of retinopathy | - Cotton wool spots especially around the optic nerve  
- Retinal hemorrhages  
- Cystoid macular edema |

<table>
<thead>
<tr>
<th>Symptoms</th>
<th>Treatment</th>
</tr>
</thead>
</table>
| - Decreased visual acuity  
- Floaters  
- Most patients are asymptomatic | - Cessation of interferon treatment  
- May require retinal consultation if complications arise |

**Differential diagnosis:**

- Interferon-associated retinopathy
- Hypertensive retinopathy
- Retinopathy from leukemia/lymphoma
- Ocular ischemia
- Purtcher’s retinopathy (see [http://eyerounds.org/cases/39-PurtschersRetinopathyAngiopathiaRetinaTraumatica.htm](http://eyerounds.org/cases/39-PurtschersRetinopathyAngiopathiaRetinaTraumatica.htm))
- HIV retinopathy
